

NRTL failure mode: collapsed activity versus weak correction

Collapse is budget/protocol-specific

short temperature proxy

NRTL almost constant
 $\text{std}(\ln \gamma_2) = 2.9 \times 10^{-4}$

final correction
inactive
 $\text{mean } |\delta| = 1.1 \times 10^{-5}$

compressed predictions
 $\text{std}(\text{pred})/\text{std}(\text{true}) = 0.227$

level errors are expected:
activity is almost absent

medium scaffold run

τ varies, but stays
bounded
 $\text{abs}(\tau) > 8$ below 0.2%

correction still weak
MAE 1.814 $\rightarrow$ 1.816

crystal dominates
 $\text{median } |\Phi|/|\text{activity}| = 12.3$

not a pure numeric blow-up:
the signal allocation is wrong
