

When do reference physical inputs help a learned solubility model?

a The pipeline, and the substitution

b Where the error sits

59 strata, Delaware (UD) profiles ($n = 477$), $(\ln \gamma)^2$

 the inputs, at most  the fixed map, at least

glycol ethers — stands: bounded, stable, positive

water — not established

dropping a laboratory flips the sign

aprotic acceptors (no O-H/N-H) — not established

the bound runs past the total error

0 0.5 1.0 1.5 2.0

The input bound moves 2-fold; the error, 25-fold.
